

TITLE OF THE INVENTION
IMAGE SENSING APPARATUS, IMAGE CAPTURE APPARATUS, THEIR
CONTROL METHOD, AND COMPUTER PROGRAM PRODUCT

5 FIELD OF THE INVENTION

The present invention relates to an image sensing apparatus which executes exposure control using object luminance information, an image capture apparatus, their control method, and a computer program product.

10

BACKGROUND OF THE INVENTION

An image sensing apparatus such as a digital still camera or the like, which comprises an electronic viewfinder (to be abbreviated as an EVF hereinafter) that displays the output from an image sensing element on a display device to confirm the composition and exposure upon actual image sensing as a viewfinder, has been proposed.

Also, in an image sensing apparatus such as a digital still camera or the like, a method of computing the exposure level by measuring the object luminance on the basis of a sensed image signal output from an image sensing element has been conventionally proposed.

As photometry methods of these image sensing apparatuses to measure the object luminance, center-weighted photometry that computes a target

luminance by weighting with predetermined coefficients using the central region of a screen as the center on the basis of a sensed image signal of a specific region of the screen or sensed image signals of a plurality of
5 divided regions, and evaluative photometry that computes a target luminance using a specific algorithm on the basis of information of each region are known.

Also, an image sensing apparatus which comprises an exposure correction function of correcting the
10 exposure value in accordance with the photographer's will irrespective of the photometry method is generally known.

An example will be explained below.

Fig. 11 is a block diagram of a digital still
15 camera.

Referring to Fig. 11, reference numeral 1 denotes an optical lens for forming an optical image on an image sensing element. The optical lens 1 includes a focus lens (not shown) for focus adjustment. Reference
20 numeral 2 denotes a stop & shutter which has both stop and shutter functions; and 3, a driving circuit for mechanical units of the optical lens 1 and stop & shutter 2. Reference numeral 4 denotes an image sensing element for converting an object image formed
25 by the optical lens into an electrical signal; 5, a timing signal generation circuit (to be abbreviated as

TG hereinafter) for generating timing signals required for operating the image sensing element; 6, an image sensing element driving circuit for amplifying a signal from the TG to a level at which the image sensing
5 element can be driven; 7, a pre-processing circuit which comprises a CDS circuit and amplifier circuit used to reduce output noise of the image sensing element 4; 8, an A/D converter; 9, a sensed image signal processing circuit; 10, a recording medium which
10 comprises, e.g., a memory card that complies with PCMCIA standards, hard disk, or the like; and 11, an interface circuit for recording a signal on the recording medium 10. Reference numeral 12 denotes a system controller serving as a control CPU for
15 controlling the respective mechanisms, a console, and the sensed image signal processing circuit; 13, a console used to externally control the camera; 14, a display signal processing circuit for displaying a signal on a display device; 15, a D/A converter; and 16,
20 a display device used as a viewfinder.

In the image sensing apparatus shown in Fig. 11, when the photographer operates the console 13 to start viewfinder display, the mechanism driving circuit 3 is driven under the control of the system controller 12 to
25 supply electric power to respective image sensing circuits. The stop & mechanical shutter 2 is driven to

a predetermined default aperture size to start exposure of the image sensing element, and electronic shutter and read pulses are supplied from the TG 5 to the image sensing element 4 via the image sensing element driving
5 circuit 6 so as to accumulate a photocharge for only a predetermined default exposure time. The signal read in the aforementioned state is converted into a luminance level signal for photometry and a viewfinder output signal by the sensed image signal processing
10 circuit 9 via the pre-processing circuit 7 and A/D converter 8. The luminance level signal is sent to the system controller 12, which determines an exposure value corresponding to the luminance level, computes an aperture value and shutter speed in correspondence with
15 the exposure value, and controls the stop & mechanical shutter 2 and electronic shutter for the next exposure in accordance with the obtained values. After that, photometry is repeated in units of fields to control exposure. The viewfinder output signal is sent to the
20 display device 16 via the D/A converter 15 and display signal processing circuit 14. The display device 16 displays an object which is being sensed.

<Photometry of Each Frame>

The operation inside the system controller upon
25 photometry will be explained below. In Fig. 11, the sensed image signal processing circuit 9 sends, to the

system controller 12, luminance values YA, YB, and YC respectively obtained by integrating signals on screen regions A, B, and C shown in Fig. 12.

The photometry process in the system controller
5 will be explained below. Let Sa, Sb, and Sc be the areas of the screen regions A, B, and C. Then, luminance values Ya, Yb, and Yc per unit area of the screen regions A, B, and C are respectively given by:

$$\begin{aligned} Y_a &= Y_A/S_a \\ 10 \quad Y_b &= Y_B/S_b \\ Y_c &= Y_C/S_c \end{aligned}$$

By computing the logarithms of differences from a predetermined luminance level reference value Yref, differences from appropriate luminance levels of the
15 respective frames are respectively obtained as dEv_a, dEv_b, and dEv_c:

$$\begin{aligned} dEv_a &= \log_2(Y_a/Y_{ref}) \\ dEv_b &= \log_2(Y_b/Y_{ref}) \\ dEv_c &= \log_2(Y_c/Y_{ref}) \end{aligned}$$

20 On the other hand, let Av0 be an Av value obtained by converting the aperture size set in the stop & mechanical shutter 2 upon exposure, and Tv0 be a Tv value obtained by converting an exposure time. Then, Ev0 as a set Ev value upon exposure is given by:

$$25 \quad Ev0 = Av0 + Tv0$$

The Ev values of the respective frames are respectively given by:

$$Ev_a = Ev0 + dEv_a$$

$$Ev_b = Ev0 + dEv_b$$

5 $Ev_c = Ev0 + dEv_c$

<Averaging Photometry>

Let Ev1 be the luminance level of the entire screen, which is obtained by weighting the regions A, B, and C in accordance with their areas, and is given by:

10
$$Ev1 = Ev0 + (dEv_a \times Sa + dEv_b \times Sb + dEv_c \times Sc) / (Sa + Sb + Sc)$$

<Center-weighted Photometry>

On the other hand, let Ev2 be the luminance level of the entire screen obtained by weighting the regions A, B, and C using predetermined weighting coefficients kWeiA, kWeiB, and kWeiC as per:

15
$$Ev2 = Ev0 + (dEv_a \times kWeiA + dEv_b \times kWeiB + dEv_c \times kWeiC) / (kWeiA + kWeiB + kWeiC)$$

Note that weighting coefficients kWeiA, kWeiB, and kWeiC are set to satisfy:

$$(kWeiA/Sa) > (kWeiB/Sb) > (kWeiC/Sc)$$

so as to achieve center-weighted photometry.

<Evaluative Photometry>

The luminance differences between the regions A and B, and B and C are given by:

$$\delta BA = Ev_b - Ev_a$$

$$\text{deltaCB} = \text{Ev}_c - \text{Ev}_b$$

An exposure correction value α of evaluative photometry is computed from the values deltaBA and deltaCB. For example, it is determined that the luminance of the screen central portion is lower, i.e., the degree of back light is larger with increasing values deltaBA and deltaCB, and α is increased to attain back light correction.

Let Ev3:

$$\text{Ev3} = \text{Ev2} - \alpha$$

be the target luminance level obtained by correcting α .

Using Ev1, Ev2, and Ev3 as exposure target values in the averaging, center-weighted, and evaluative photometry modes, respectively, various photometry schemes can be provided.

<Exposure Correction>

When $\text{Comp}\beta$ represents an exposure correction value set when the photographer operates the console 13, and Ev4, Ev5, and Ev6 represent the sums of the exposure target values Ev1, Ev2, and Ev3

$$\text{Ev4} = \text{Ev1} + \text{Comp}\beta \text{ (averaging photometry)}$$

$$\text{Ev5} = \text{Ev2} + \text{Comp}\beta \text{ (center-weighted photometry)}$$

$$\text{Ev6} = \text{Ev3} + \text{Comp}\beta \text{ (evaluative photometry)}$$

in the respective photometry mode and $\text{Comp}\beta$, i.e., exposure target values upon setting exposure correction,

an image sensing apparatus with an exposure correction function can be provided.

<AE During EVF Display>

In an EVF display mode, photometry for obtaining
5 an exposure target value and exposure as image sensing for EVF display must be simultaneously done.

Hence, when Ev0 as the luminance value upon exposure adopts an exposure target value computed upon exposure one or more cycles before, an exposure result
10 corresponding to the selected photometry mode and exposure correction value can always be confirmed on the EVF.

As a versatile image sensing element used in the image sensing apparatus such as a digital still camera
15 or the like, a CCD is known. The CCD can measure a luminance range of around 8EV.

Since the luminance range of a general object is around 5EV, the luminance of the object can be accurately measured by setting the object central
20 luminance as the center of the luminance distribution of the object to be close to the photometry central luminance as the center of the luminance range measured by the CCD.

In a still camera with an EVF, by displaying an
25 image sensed using an exposure value equivalent to the exposure target value upon actual image sensing on the

EVF, whether or not exposure of the image is appropriate can be estimated in advance. For this purpose, in the EVF display mode, photometry for computing an exposure target value and exposure for
5 sensing an EVF display image are simultaneously done. Hence, the exposure target value inevitably matches the photometry central luminance in this case.

However, when evaluative photometry or exposure correction is done, as described above, the exposure
10 target value does not often match the object central luminance, and has a difference of several EV in some cases. That is, since the photometry central luminance is separated from the object central luminance, the object luminance range readily falls outside the
15 photometry luminance range of the CCD, and it becomes impossible to measure the object luminance in this case.

When photometry is made using the object central luminance or an exposure target value obtained by averaging photometry irrespective of the exposure
20 target value, the luminance distribution of the object is highly likely to fall within the dynamic range of the CCD. However, the exposure result using the exposure target value of the selected photometry mode cannot be confirmed on the EVF in advance.

25

SUMMARY OF THE INVENTION

Therefore, the present invention has been made in consideration of the aforementioned problems, and has as its object to provide an image sensing apparatus, which can match the brightness of an image displayed on an EVF with a target luminance level in actual exposure even in an EVF mode, an image capture apparatus, their control method, and a computer program product.

In order to solve the aforementioned problems and to achieve the above object, an apparatus according to the present invention is characterized by comprising an image sensing sensor for converting an optical image into an image signal, a viewfinder for displaying the image signal obtained by the image sensing sensor, and a correction device for correcting brightness of the viewfinder in accordance with a difference between a luminance level of the image signal obtained by the image sensing sensor, and a target luminance level.

A control method according to the present invention is a control method for controlling an image sensing apparatus, and is characterized by comprising the step of displaying the image signal obtained by the image sensing sensor on the viewfinder, and correcting the brightness of the viewfinder in accordance with a difference between a luminance level of the image signal obtained by the image sensing sensor, and a target luminance level.

A computer program product according to the present invention is a computer program product that supplies a control program of an image sensing apparatus, and is characterized by including a content
5 of displaying the image signal obtained by the image sensing sensor on the viewfinder, and correcting the brightness of the viewfinder in accordance with a difference between a luminance level of the image signal obtained by the image sensing sensor, and a
10 target luminance level.

Other objects and advantages besides those discussed above shall be apparent to those skilled in the art from the description of a preferred embodiment of the invention which follows. In the description,
15 reference is made to accompanying drawings, which form a part hereof, and which illustrate an example of the invention. Such example, however, is not exhaustive of the various embodiments of the invention, and therefore reference is made to the claims which follow the
20 description for determining the scope of the invention.

BRIEF DESCRIPTION OF THE DRAWINGS

25 DETAILED DESCRIPTION OF THE PREFERRED EMBODIMENTS

The preferred embodiments of the present invention will be described in detail hereinafter with reference to the accompanying drawings.

[First Embodiment]

5 Fig. 1 is a block diagram showing the arrangement of the first embodiment of an image sensing apparatus according to the present invention. Since reference numerals 1 to 16 correspond to those in the block diagram shown in Fig. 11, a description thereof will be
10 omitted.

 The photometry operation in the first embodiment will be explained below.

 In Fig. 1, a sensed image signal processing circuit 9 sends luminance values $Ys1$ to $Ys36$ obtained
15 by integrating signals on divided screen regions $S1$ to $S36$ shown in Fig. 2 to a system controller 12. Since all the regions $S1$ to $S36$ have an identical area, $Ys1$ to $Ys36$ can be considered as the luminance values per unit area.

20 The photometry process in the system controller will be explained below with reference to the flow charts shown in Figs. 3A to 3C.

 Step $S1$: By computing differences from a predetermined luminance level reference value $Yref$ as
25 logarithms, differences from appropriate luminance

levels of respective frames are obtained as dEv_Sn ($n = 1$ to 36)

$$dEv_Sn = \log_2(Y_{sn}/Y_{ref})$$

Step S2: Let $Av0$ be an Av value obtained by
5 converting an aperture size set in a stop & shutter 2
upon exposure, and $Tv0$ be a Tv value obtained by
converting an exposure time. Then, set $Ev0$ upon
exposure is obtained as

$$Ev0 = Av0 + Tv0$$

10 Step S3: The Ev values of the respective frames
are given by:

$$Ev_Sn = Ev0 + dEv_Sn \quad (n = 1 \text{ to } 36)$$

Then, the object central luminance is obtained.

Step S4: The values Ev_S1 to Ev_S36 are sorted
15 and the sorted values are named $E(1)$, $E(2)$, $E(3)$, ...,
 $E(36)$ in ascending order.

Step S5: The object central luminance is
computed.

An example of the method of computing the object
20 central luminance will be explained below with
reference to the flow chart in Fig. 4.

Step S101: A loop counter i is reset to zero.

Step S102: $E(1+i)$ and $E(36-i)$ are respectively
substituted in variables E_{min} and E_{max} .

25 Step S103: The difference between E_{min} and E_{max}
is computed, and is compared with a predetermined value

Edyna. Note that Edyna is the predetermined value obtained based on the dynamic range of the CCD. If the difference between Emin and Emax is smaller than Edyna, since it is determined that values ranging from $E(1+i)$ to $E(36-i)$ fall within the photometry range in single exposure, the control leaves the loop, and the flow advances to step S6.

Step S104: i is incremented.

Step S105: The loop repeats itself while $i \leq 18$.

10 Step S106: A value obtained by dividing the sum of Emax and Emin by 2 is set to be an object central luminance E_c .

Step S6: It is checked if exposure correction is set at a console 13.

15 Steps S7 and S8: A photometry mode set at the console 13 is discriminated.

Step S9: If it is determined in step S6 that no exposure correction is set and it is determined in step S7 that the photometry mode is a center-weighted photometry mode, an exposure target value Ev_2 of center-weighted photometry is computed.

20 Step S10: If it is determined in step S6 that no exposure correction is set and it is determined in step S7 that the photometry mode is an evaluative photometry mode, an exposure target value Ev_3 of evaluative photometry is computed.

Step S11: If it is determined in step S6 that exposure correction is set and it is determined in step S8 that the photometry mode is the center-weighted photometry mode, an exposure target value Ev5 upon making exposure correction in center-weighted photometry is computed.

Step S12: If it is determined in step S6 that exposure correction is set and it is determined in step S7 that the photometry mode is the evaluative photometry mode, an exposure target value Ev6 upon making exposure correction in evaluative photometry is computed.

Note that the exposure target values in steps S9 to S12 are computed as follows. That is, let YA, YB, and YC be the sums of those included in hatched portions shown in Figs. 5, 6, and 7 of the luminance values Ys1 to Ys36, which are integrated in units of screen regions S1 to S36 shown in Fig. 2. Then, YA, YB, and YC are equivalent to the luminance values of the screen regions A, B, and C shown in Fig. 12. Hence, the exposure target values Ev2 of center-weighted photometry, the exposure target value Ev3 of evaluative photometry, the exposure target value Ev5 upon making exposure correction in center-weighted photometry, and the exposure target value Ev6 upon making exposure correction in evaluative photometry can be respectively

computed using methods equivalent to those described above.

Step S13: An aperture value AvC and shutter speed value TvC which are obtained by applying the
5 object central luminance Ec to the program graph shown in Fig. 8 are set.

In the image sensing apparatus shown in Fig. 1,
the aperture value of the stop & mechanical shutter 2
is set at AvC , and electronic shutter and read pulses
10 are supplied from a TG 5 to an image sensing element 4
via an image sensing element driving circuit 6 to
accumulate a photocharge for an exposure time
corresponding to TvC . A signal read in the
aforementioned state is converted into a viewfinder
15 output signal by the sensed image signal processing
circuit 9 via a pre-processing circuit 7 and A/D
converter 8, and the converted signal is sent to a
display device 16 via a D/A converter 15 and display
signal processing circuit 14.

20 Steps S14 to S20: The system controller 12
selects one of the exposure target values $Ev2$ of
center-weighted photometry, the exposure target value
 $Ev3$ of evaluative photometry, the exposure target value
 $Ev5$ upon making exposure correction in center-weighted
25 photometry, and the exposure target value $Ev6$ upon
making exposure correction in evaluative photometry in

accordance with the photometry mode and exposure
correction value set at the console 13, and computes a
difference Edef between the selected value and object
central luminance Ec. For example, if the photometry
5 mode is evaluative photometry and exposure correction
is set, Edef is given by:

$$Edef = Ev6 - Ec$$

Step S21: The system controller 12 inputs a
signal corresponding to the value Edef to the display
10 signal processing circuit 14, which adjusts the gain
and offset level of an analog video signal to be output
to the display device 16 in accordance with the input
signal, thus realizing EVF display having brightness
equivalent to the exposure target value.

15 Steps S22 to S29: While driving the EVF in this
state, if the photographer has pressed the shutter
release button on the console 13, the system controller
12 selects one of the exposure target values Ev2 of
center-weighted photometry, the exposure target value
20 Ev3 of evaluative photometry, the exposure target value
Ev5 upon making exposure correction in center-weighted
photometry, and the exposure target value Ev6 upon
making exposure correction in evaluative photometry in
accordance with the photometry mode and exposure
25 correction value set by the photographer at the console
13, and sets the selected value as an exposure value

EvS of actual exposure (image sensing). For example, if the photometry mode is evaluative photometry and exposure correction is set, EvS is:

$$\text{EvS} = \text{Ev6}$$

5 Step S30: An aperture value AvS and shutter speed value TvS obtained by applying the exposure value EvS of actual exposure to the program graph shown in Fig. 8 are set to determine an exposure value in actual exposure, and exposure control for actual exposure is
10 executed.

[Second Embodiment]

 Figs. 9A to 9C are flow charts showing the photometry process in the system controller according to the second embodiment of the present invention.
15 Since the arrangement of the image sensing apparatus is the same as that in the first embodiment, a description thereof will be omitted.

 In Figs. 9A to 9C, steps S1 to S20, and S21 are the same as those in the first embodiment except that
20 there is not step 13.

 Step S31: The system controller 12 compares the value Edef with a predetermined value.

 Step S32: If Edef is larger than the predetermined value, an aperture value AvC and shutter
25 speed value TvC obtained by applying the object central luminance Ec obtained in step S5 to the program graph

shown in Fig. 8 are set, and the flow advances to step S21. After that, the same operation as in the first embodiment is done.

Step S33: If Edef is smaller than the
5 predetermined value, an aperture value AvS and shutter speed value TvS obtained by applying the exposure target value obtained in one of steps S9 to S12 to the program graph shown in Fig. 8 are set, and the flow advances to step S22. After that, the same operation
10 as in the first embodiment is done. In this case, the display signal processing circuit 14 skips step S21 of adjusting the gain and offset level of an analog video signal with respect to the display device 16.

[Third Embodiment]

15 Fig. 10 is a block diagram showing the arrangement of the third embodiment of an image sensing apparatus of the present invention.

Unlike in the first and second embodiments, the system controller 12 inputs a signal corresponding to
20 the value Edef to the display signal processing circuit 14, which adjusts the gain and offset level of a digital video signal to be output to the display device 16, thus achieving EVF display having brightness equivalent to the exposure target value.

25 Note that the average luminance may be used in place of the object central luminance.

Also, the exposure value may be limited by controlling the shutter speed or aperture value alone.

Furthermore, gain adjustment may be implemented by changing the reference voltage of the D/A converter
5 15.

[Another Embodiment]

Note that the present invention may be applied to either a system constituted by a plurality of devices (e.g., a host computer, an interface device, a reader,
10 a printer, and the like), or an apparatus consisting of a single equipment (e.g., a copying machine, a facsimile apparatus, or the like).

The objects of the present invention are also achieved by supplying a storage medium, which records a
15 program code of a software program that can implement the functions of the above-mentioned embodiments to the system or apparatus, and reading out and executing the program code stored in the storage medium by a computer (or a CPU or MPU) of the system or apparatus.

20 In this case, the program code itself read out from the storage medium implements the functions of the above-mentioned embodiments, and the storage medium which stores the program code constitutes the present invention.

25 As the storage medium for supplying the program code, for example, a floppy disk, hard disk, optical

disk, magneto-optical disk, CD-ROM, CD-R, magnetic tape, nonvolatile memory card, ROM, and the like may be used.

The functions of the above-mentioned embodiments may be implemented not only by executing the readout
5 program code by the computer but also by some or all of actual processing operations executed by an OS (operating system) running on the computer on the basis of an instruction of the program code.

Furthermore, the functions of the above-mentioned
10 embodiments may be implemented by some or all of actual processing operations executed by a CPU or the like arranged in a function extension board or a function extension unit, which is inserted in or connected to the computer, after the program code read out from the
15 storage medium is written in a memory of the extension board or unit.

The embodiments of the present invention have been explained. However, the present invention is not limited to the arrangements of these specific
20 embodiments, and may be applied to any other arrangements as long as they can achieve the functions described in the appended claims or those of the arrangements of the embodiments.

The software and hardware arrangements of the
25 aforementioned embodiments can be replaced as needed.

Also, the present invention may combine the
aforementioned embodiments or their technical elements.

Furthermore, the present invention may be applied
to a single apparatus formed by the overall or partial
5 arrangement of the appended claims or embodiments, an
apparatus combined with another apparatus, or a
component that forms an apparatus.

Moreover, the present invention may be applied to
various kinds of cameras such as a digital camera for
10 sensing a moving or still image, a camera using a
silver halide film, a single-lens reflex camera, a lens
shutter camera, a monitor camera, and the like, an
image sensing apparatus other than a camera, an image
scanning apparatus, an optical apparatus, and the like,
15 devices applied to these camera, image sensing
apparatus, image scanning apparatus, optical apparatus,
and the like, building components of these apparatuses,
control methods of these apparatuses, and a medium such
as a computer readable storage medium that supplies a
20 control program of these apparatuses.

As described above, according to the above
embodiments, more accurate photometry and confirmation
of the target luminance level on the EVF can be
achieved at the same time.

25 The present invention is not limited to the above
embodiments and various changes and modifications can

be made within the spirit and scope of the present invention. Therefore, to apprise the public of the scope of the present invention the following claims are made.

1. A method of determining the presence of a substance in a sample, comprising the steps of: (a) providing a sample; (b) providing a reagent; (c) reacting the sample with the reagent; (d) observing the reaction; and (e) determining the presence of the substance based on the observation.
